Fig. 5 Structured illumination microscopy. (a) Fourier domain representation of conventional, linear, and nonlinear structured illumination microscopy. In conventional microscopy, the measurable spatial frequency range is given as $|\vec{k}| > (2/\lambda) \cdot NA$. In linear structured illumination, spatial frequency information of the sample is laterally shifted an amount corresponding to the period of the illuminating pattern. Therefore, the high-spatial frequencies beyond the conventional imaging system become observable. In nonlinear structured illumination, the spatial frequency information of the sample is shifted corresponding to integer multiples of the pattern's frequency. With pattern rotation, a large spatial frequency range can be collected. (b) A mammalian CHO cell imaged by the nonlinear structured illumination microscopy. Panel (b) is modified from Ref. 124.
